Graph/Figure

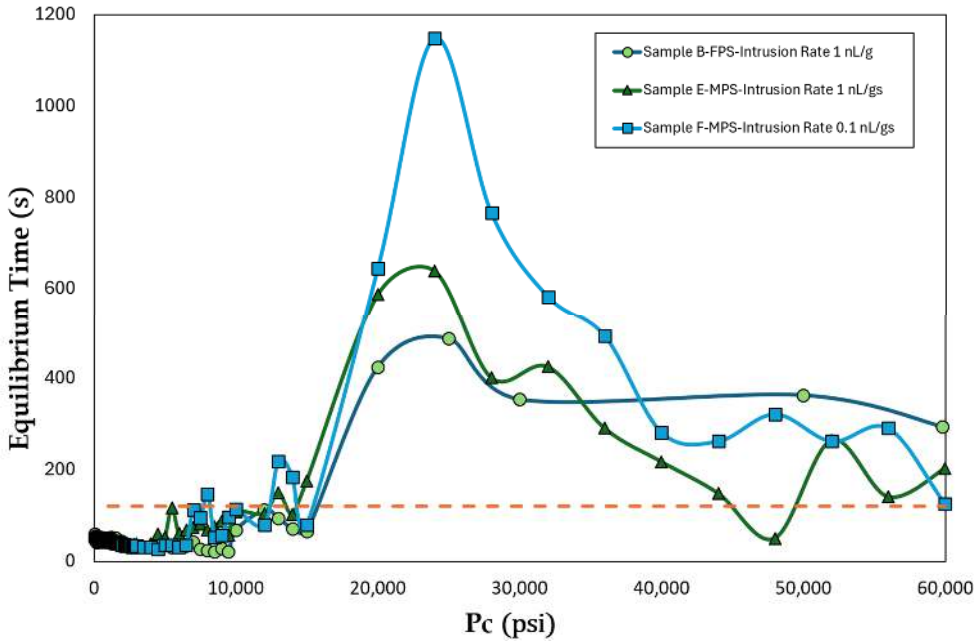

Figure 1. Equilibration time at each pressure step during constant-intrusion-rate mercury intrusion MICP tests performed using fewer pressure steps (FPS), more pressure steps (MPS), and intrusion rates of 1 and 0.1 nL g^{-1} s^{-1} (where nL denotes nanoliters). The sharp increase in equilibration time marks the capillary entry pressure, while lower intrusion rates require longer equilibration times following mercury entry.
